Switching assembly having an inlet way and five oulet ways for faucet components (54)

(57)A switching assembly having at least an inlet way (21) and a plurality of outlet ways (15) for faucet components, in particular for selectively supplying fittings of a multi-function shower box, comprises a central body (2) operating as a support element thereabout can rotate an entraining element (3) of a movable disc (4) for selecting several supply circuits coupled to the respective fittings.

The movable disc comprises at least a port (14) for respectively communicating one of the holes (15) of a fixed disc (10) with a delivery chamber (16) defined between the central body and an outer casing (5), the outer casing (5) holding therein the switching devices.

The switching assembly is characterized in that the outer casing (5) further houses therein a valve body (22) for shutting-off the water flow supplied to the inlet way (21) or path.

1

Description

BACKGROUND OF THE INVENTION

[0001] The present invention relates to a switching assembly having an inlet way or path and five outlet ways for faucet components, in particular for selectively water supplying different fittings of a multi-function shower hav

[0002] Shower boxes or cabins provided with several fittings allowing to deliver water through a manual shower element, a shower top blower assembly, a plurality of side jets, a foot washing outlet and an outlet for water supplying a basin included in the shower box are already known.

SUMMARY OF THE INVENTION

[0003] The aim of the present invention is to provide a switching assembly, having an inlet way and five outlet ways, specifically designed for selectively water supplying the fittings of a multi-function shower box, in which the device allowing to selectively switch the water flow toward one of the fittings are separated and independent from the valve body integrated in the switching assembly.

[0004] Within the scope of the above mentioned aim, a main object of the present invention is to provide such a switching assembly having a very high mechanical strength, together with very good sliding characteristics for sliding elements forming the switching devices thereof

[0005] Another object of the present invention is to provide such a switching assembly having an inlet way and five outlet ways, including a movable ceramics disc which is perfectly balanced and adapted to facilitate the mutual rotary movement with respect to the fixed ceramics disc, even under a high pressure condition.

[0006] Another object of the present invention is to provide such a switching assembly providing perfect sealing characteristics at the outlet of the fixed ceramics disc, even after a very long use time period.

[0007] Yet another object of the present invention is to provide such a switching assembly which can be easily made by conventional processing methods and which, moreover, is very competitive from a mere economic standpoint.

[0008] According to one aspect of the present invention, the above mentioned aim and objects, as well as yet other objects, which will become more apparent hereinafter, are achieved by a switching assembly, having at least an inlet way and a plurality of outlet ways for faucet components, in particular for selectively water supplying fittings of a multifunction shower box, comprising a central body operating as a support element, thereabout can rotate an entraining element of a movable disc for selecting water supplying circuits coupled to said fittings, said movable disc comprising at least a port

for respectively communicating one of the holes of a fixed disc with a delivery chamber defined between the central body and an outer casing, said outer casing of said switching assembly holding therein the switching devices, and being characterized in that said outer casing further includes therein a valve body for shutting off the water flow supplied to the inlet way.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] Further characteristics and advantages of the present invention will become more apparent hereinafter from the following detailed disclosure of a preferred, though not exclusive, embodiment of the invention, which is illustrated, by way of an indicative, but not limitative, example in the accompanying drawings, where:

Figure 1 is a cross-sectional elevation view of the switching assembly according to the present invention; and

Figure 2 is a bottom plan view of the housing of the cartridge applied to the switching assembly according to the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0010] With reference to the number references of the above mentioned figures, the switching assembly according to the present invention, which has been generally indicated by the reference number 1, comprises a central body 2, made of brass or any other suitable materials, operating as a support element thereabout rotates an entrainment or driving element 3 of a ceramics disc 4, for selecting a plurality of water supplying circuits coupled to respective fittings.

[0011] The ceramics disc 4 comprises at least a communicating port 14 for respectively communicating one holes of the holes 15 of a bottom fixed disc 10 with the delivery chamber 16 defined between the central body 2 and a top outer casing 5.

[0012] Above the ceramics disc 4 is mounted a ring element 6 including a peripheral resilient tooth element 6', which is rotatively driven by the entrainment or driving element 3.

[0013] As the resilient tooth element 6' is rotatively driven, it engages with radially extending cavities 17, suitably formed on the inner surface of the top outer casing 5.

[0014] The top outer casing 5, in turn, is made rigid with a bottom outer casing 18, for example by an ultrasound welding method, thereby providing a monolithic outer casing for receiving therein a cartridge assembly.

[0015] More specifically, the bottom outer casing 18 is provided for holding therein the fixed disc 10 and bottom portion of the central body 2, which bottom portion is locked with respect to the bottom outer casing 18 by a threaded locking element 9 which extends outside of the outer casing.

[0016] Thus, the threaded locking element 9, screw engaged at the bottom portion of the central body 2, provides a removable coupling of the elements constituting an integrating portion of the cartridge assembly.

[0017] As shown, the threaded locking element 9 is axially perforated in order to allow inlet water to pass therethrough toward the delivery region 20 inside the central body 2.

[0018] The water flow can be shut-off at the delivery region 20 by a shut-off or closing device, or valve body, such as a screw element 22 including a driving rod 7 to which a driving knob, not shown, can be coupled.

[0019] The valve body, in turn, can be integrated into the switching assembly, as in the shown embodiment, or the water supply to the switching assembly can be achieved by a separated valve body, according to the assembling requirements.

[0020] If the water flow is not locked by the screw element 22, then water coming from the central passage 21 of the central body 2 will enter the delivery region 20 and through the radially extending holes 23, said water will enter the delivery chamber 16 defined between the central body 2 and top outer casing 5.

[0021] From the water delivery chamber 16, water can pass through one of the selected peripheral outlet holes 15, by rotating the ceramics disc 4 through the entrainment or driving element 3.

[0022] To that end, the driving element 3 comprises a thread and slot 8, for allowing a water jet selecting knob to be coupled thereto, said jets being not specifically shown.

[0023] The top portion of the outer casing 5 operates as a holding element for the fixed disc 10, through which are formed the peripheral outlet holes or ports 15.

[0024] The disclosed construction prevents the fixed disc 10 from being undesirably raised under the urging force provided by the seals 11 which, in prior switching cartridges generate a great friction between the fixed disc and movable disc, thereby hindering a proper rotary movement for selecting the water flows.

[0025] It has been found that the invention fully achieves the intended aim and objects.

[0026] In fact, the invention provides a switching assembly, having an inlet way and five outlet ways, which can selectively water supply several fittings of a multifunction shower box, and in which the switching devices for selectively switching the water flow toward one of the fittings, are separated and independent from the valve body integrated in the switching assembly.

[0027] An important advantage of the invention, in fact, consists of the possibility of integrating the valve body in the switching assembly, as in the shown embodiment, or to control the water supply by means of a separated valve body, according to the assembling requirements.

[0028] The separation of the water switching and shut-off functions is moreover advantageous for maintenance or servicing operations, since it would be pos-

sible to replace the valve body without affecting the switching devices.

[0029] Moreover, it is possible to use standard valve bodies.

[0030] Yet another advantage of the present invention is that the switching assembly can be easily and smoothly operated, since the movable sliding parts have been designed for sliding with a very reduced friction.

[0031] Furthermore, the used materials, as well as the contingent size and shapes, can be any, depending on requirements.

Claims

15

25

30

35

- 1. A switching assembly, having at least an inlet way and a plurality of outlet ways for faucet components, in particular for selectively water supplying fittings of a multifunction shower box, comprising a central body operating as a support element, thereabout can rotate an entraining element of a movable disc for selecting water supplying circuits coupled to said fittings, said movable disc comprising at least a port for respectively communicating one of the holes of a fixed disc with a delivery chamber defined between the central body and an outer casing, said outer casing of said switching assembly holding therein the switching devices, and being characterized in that said outer casing further includes therein a valve body for shutting off the water flow supplied to the inlet way.
- 2. A switching assembly, according to Claim 1, characterized in that said outer casing comprises a top outer casing and a bottom outer casing, the top outer casing being rigid with the bottom outer casing by an ultrasound weldment, thereby providing a single-piece outer casing.
- 40 3. A switching assembly, according to Claims 1 and 2, characterized in that said bottom outer casing is designed for holding therein the fixed ceramics disc and a bottom portion of the central body, which bottom portion can be locked with respect to the bottom outer casing by a locking threaded element extending outside of the outer casing.
 - 4. A switching assembly, according to one or more of the preceding claims, characterized in that said locking threaded element is axially perforated for allowing inlet water to pass therethrough toward a delivery region inside the central body.
- 5. A switching assembly, according to one or more of the preceding claims, **characterized in that** a ring element is mounted on the top of the movable disc.
 - 6. A switching assembly, according to one or more of

50

the preceding claims, characterized in that said ring element comprises a peripheral elastic tooth element and being driven by a driving element and that said elastic tooth element engages, as it is rotated, with radially extending cavities formed on an inner surface of said top outer casing.

7. A switching assembly, according to one or more of the preceding claims, characterized in that the water supply flow can be shut-off, at the delivery region, by the valve body comprising a screw element including a control rod to which a control knob is connected.

8. A switching assembly, according to one or more of 15 the preceding claims, characterized in that said switching assembly comprises one or more of the disclosed and/or illustrated features.
